

## **Arkansas Game and Fish Commission Aerial Waterfowl Survey Report January 4 and 6-9, 2020**

Arkansas Game and Fish Commission staff conducted the annual midwinter waterfowl survey Jan. 4 in the Arkansas River Valley and Jan. 6-9 in Mississippi Alluvial Valley (Delta). As a reminder, the Bigelow-Lake Conway and Cadron survey zones were cut from the Arkansas River Valley survey due to consistently low duck counts. Staff conducted the southwest Arkansas cruise surveys Jan. 9. Observers estimated 1.4 million total ducks in the Delta, half of which were mallards (729,960; Table 1). Duck population estimates in the Arkansas River Valley totaled just over 34,000, including slightly under 21,000 mallards (Table 2), while only about 2,000 mallards were counted among slightly less than 27,000 total ducks in southwest Arkansas. Observers in the Delta estimated more than 1.3 million light (lesser snow and Ross's) geese and about 320,000 greater white-fronted geese during this survey, with the caveat that this survey is not great for estimating goose numbers. Observers were Jason Carbaugh, Jason Jackson, Jeff Lawson, Cameron Tatom and Alex Zachary.

The Delta mallard population estimate is slightly less than the 2010-2020 long-term midwinter survey average of about 859,000. However, the total duck population estimate was above the long-term average of over 1.2 million (Figure 1). The big departure from patterns this decade was the species composition of ducks observed during this survey. Mallards typically account for nearly 70% of all ducks during the midwinter survey; this year's mallard percentage was only 50%. Population estimates for northern pintails, northern shovelers and gadwalls were noticeably higher than usual. Similar to the Delta, these species accounted for nearly all the non-mallard ducks in both the Arkansas River Valley and southwest Arkansas.

Observers estimated the greatest number of mallards in the Delta in the Lower St. Francis survey zone, while estimates were somewhat low in other zones. In fact, mallard estimates declined from December in several zones (Cache, Black-Upper White and Bayou Meto-Lower Arkansas) that traditionally are mallard strongholds. Duck density maps show this distribution pattern, with several duck hotspots (Figure 3) that were slightly different than mallard hotspots (Figure 4); non-mallard hotspots appear to be driven by pintail distribution. Estimates for all ducks and mallards in the Arkansas River Valley were more than 40% below and more than 30% below average, respectively (Figure 2), with the highest mallard and total duck estimates in the East Dardanelle, Holla Bend and Point Remove-Plumerville survey zones. In the Arkansas River Valley, duck (Figure 5) and mallard (Figure 6) concentrations centered around Holla Bend National Wildlife Refuge and Ed Gordon Point Remove Wildlife Management Area and toward the eastern end of Dardanelle Reservoir. Many of the pintails, shovelers and gadwall occurred in the Delta south of the Arkansas River and east of Crowley's Ridge.

Similar to observations throughout this wintering periods, ducks were concentrated on established waterfowl sanctuaries and habitats that appeared not to be purposefully managed or actively hunted. A region where this seemed more evident was south of Marked Tree, past I-40, and east to the Mississippi River within the Lower St. Francis survey zone. Although Big Lake NWR/WMA had a good concentration of ducks, it was not as impressive as the December survey. Observers flying transects within this survey zone noted several fields full of ducks, some on transect lines and some in transition areas between randomly selected transect lines. Perhaps many of the ducks around Big Lake much of the wintering period moved south to feed in these fields. There were large fields (not the typical 40 acre square, but >100 acres) near the Mississippi River that had a low end or swale running through the middle that had water and ducks. Most of these had no pits, blinds or evidence of hunting activity present. Similar to previous surveys, ducks were using moist-soil habitat or fields

that did not get planted this spring that had moist-soil vegetation present, again without evidence of duck hunting activity.

Statewide habitat availability generally has been low this wintering period. Overbank flooding along a few river corridors early in duck season was short-lived, and the rainfall necessary to produce additional flooding has been mostly absent. December was dry throughout much of Arkansas, with monthly precipitation totals two to four inches below average in many locations. Portions of west Arkansas got less than an inch of rain. For example, rainfall totals were only 53%, 42% and 26% of average December totals in Jonesboro, Pine Bluff and Fort Smith, respectively. Temperatures broke record highs several times during December, especially late in the month. These weather patterns typically do not lead to high mallard counts, but early water captured in both managed and limited unmanaged habitats appears to be supporting mallard numbers at least close to average. That said, mallards have not had much reason to be attracted to Arkansas in greater numbers; extensive surface water can provide that draw. In contrast, warm conditions combined with increasing day lengths clearly provided conditions suitable for some early migrating species (e.g. northern pintails and northern shovelers) to jump back north into Arkansas from points south as they begin spring migration.

The most substantial rain event for much of the state occurred immediately following the completion of this survey. No doubt habitat availability increased rapidly and extensively across much of the Delta as a result of this storm system. Warm weather has settled in again, but much cooler temperatures are forecast for the week of Jan. 20, the same week staff will conduct the final waterfowl survey of this wintering period. The early migrant species that prospected north into Arkansas the past couple weeks likely may shift back south. Habitat availability may have increased enough this past week to attract additional mallards, but a big jump in numbers is unlikely as the wintering period comes to an end. Even so, hopefully cooler temperatures and sustained overbank flooding in some areas will lead to increased duck movement as birds seek out new habitats and improved hunting conditions as the season draws to an end.

Table 1. Waterfowl abundance estimates in Arkansas during the late November (Nov), mid-December (Dec), early-January Midwinter Survey (MWS) and late-January (Jan) aerial waterfowl survey periods, 2009-2020, in the Mississippi Alluvial Valley (MAV) using stratified random sampling of transects.

## **Survey Design Background**

The Mississippi Alluvial Valley is an area of continental significance for migrating and wintering waterfowl, as outlined in the North American Waterfowl Management Plan, and the single most important region for wintering mallards. Habitats found in western Arkansas, including the Arkansas River Valley and southwest Arkansas, such as the Red and Sulphur River floodplains, provide additional critical habitat for migrating and wintering waterfowl. Biologists conduct regular waterfowl surveys in these regions by aircraft up to four times each wintering period.

Winter waterfowl surveys, including the Midwinter Waterfowl Survey, have been conducted across much of the United States since 1935. Many different counting techniques have been used, and recently AGFC and partners have conducted surveys in the MAV using stratified random sampling of aerial fixed width (250m) strips, or transects, that have the advantages of extensive coverage (i.e., no area is excluded from the sample), increased accuracy by counting on fixed strips rather than traditional “cruise” surveys only counting waterfowl on large concentration areas, and availability of measures of sampling error.

Beginning in 2011 in the MAV, survey strata – or sampling zones – follow watershed boundaries (Figure 4). Watersheds in this case are simply land areas that are occupied by a drainage system consisting of a portion of a surface stream and all the tributary surface streams feeding it. For example, the Cache River strata includes lands surrounding and tributaries flowing into the Cache River from the Missouri border on the north to the Cache River’s junction with the White River on the south. At the root of this sampling design is the idea that habitat within these zones will share common weather and flooding patterns and, knowing that ducks are keyed in on such patterns, duck distribution will vary among watersheds. This is not a concept foreign to those who follow ducks, particularly duck hunters, as they frequently discuss habitat and duck numbers in terms of conditions in the “Cache River bottoms,” for instance. Systematically conducting aerial waterfowl surveys using this design will allow for more efficient allocation of sampling effort and provide precise estimates of waterfowl abundance in the MAV. Such a design offers an opportunity to track changes in abundance in response to changes in land use, flooding patterns or weather conditions, for example.

Before each survey period, transects to be flown are randomly selected within each strata. Biologists spend many hours in the air flying each of these transects – totaling over 3,500 miles each survey – recording all waterfowl observations using specialized computer software that collects location information in flight. Biologists also collect habitat information for each duck observation to track trends in habitat use. These data can then be used to generate population estimates for each strata and the entire MAV and develop visual representations of duck distribution (i.e., duck density maps).
